Abstract—In this paper, we describe how checking whether a given property F is true for a product $A_1 \times A_2$ of partially ordered spaces can be reduced to checking several related properties of the original spaces A_i .

I. FORMULATION OF THE PROBLEM

Degrees of certainty: from $\{0, 1\}$ to $[0, 1]$ to general partially ordered sets. In the traditional 2-valued logic, every statement is either true or false. Thus, the set of possible truth values consists of two elements: true (1) and false (0).

Fuzzy logic takes into account that people have different degrees of certainty in their statements; see, e.g., [2], [10].

Traditionally, fuzzy logic uses values from the interval $[0, 1]$ to describe uncertainty. In this interval, the order is total (linear) in the sense that for every two elements $a, a' \in [0, 1]$, either $a \leq a'$ or $a' \leq a$.

However, often, partial orders provide a more adequate description of the expert's degree of confidence. For example, since an expert cannot describe her degree of certainty by an exact number, it makes sense to describe this degree by an interval $[\underline{d}, \bar{d}]$ of possible numbers [7], [9] – and intervals are only partially ordered; e.g., the intervals $[0.5, 0.5]$ and $[0, 1]$ are not easy to compare.

More complex sets of possible degrees are also sometimes useful. Not to miss any new options, in this paper, we consider general partially ordered spaces.

Need for product operations. Often, two (or more) experts evaluate a statement S . Then, our certainty in S is described by a pair (a_1, a_2) , where $a_i \in A_i$ is the i -th expert's degree of certainty. To compare such pairs, we must therefore define a partial order on the set $A_1 \times A_2$ of all such pairs.

Two examples of product operations. One example of a partial order on $A_1 \times A_2$ is a *Cartesian* product:

$$(a_1, a_2) \leq (a'_1, a'_2) \Leftrightarrow ((a_1 \leq a'_1) \& (a_2 \leq a'_2)).$$

This product corresponds to a *cautious* approach, when our confidence in S' is higher than in S if and only if it is higher for both experts.

Another example is a *lexicographic* product:

$$(a_1, a_2) \leq (a'_1, a'_2) \Leftrightarrow$$

$$((a_1 \leq a'_1) \& a_1 \neq a'_1) \vee ((a_1 = a'_1) \& (a_2 \leq a'_2)).$$

This product corresponds to the case when we have the absolute confidence in the first expert; then, we only use the opinion of the second expert when, to the first expert, the degrees of certainty are indistinguishable.

We can have other product operations in which the relation between the pairs (a_1, a_2) and (a'_1, a'_2) is defined in terms of the relations between the elements $a_1, a'_1 \in A_1$ and between the elements $a_2, a'_2 \in A_2$.

A natural question. Once a product is defined, it is reasonable to ask when the resulting partially ordered set $A_1 \times A_2$ it satisfies a certain property: is it a total order? is it a lattice order? etc. It is desirable to have some criteria that would transform the question about the product space into questions about related properties of component spaces.

Some such criteria are known (see, e.g., [13] and references therein). For example:

- A Cartesian product is a total order if and only if one of the components is a total order, and the other consists of a single element.
- A lexicographic product is a total order if and only if both components are totally ordered.

What we do in this paper. In this paper, we provide a general algorithm that reduced the question whether a certain property is satisfied for a product to several properties of component spaces.

Applications beyond logic. Similar questions arise in other applications of ordered sets, e.g., in space-time geometry where the causality ordering relation $a \leq b$ means that an event a can influence the event b ; see, e.g., [1], [3], [4], [5], [6], [8], [11], [12].

Applications beyond orders. Our algorithm does not use the fact that the original relations are orders (i.e., transitive antisymmetric relations). Thus, our algorithm is applicable to a general case when we have an arbitrary binary relation – equivalence, similarity, etc. Moreover, this algorithm can be

applied to the case when we have a space with *several* binary relations – e.g., an order relation and a similarity relation.

II. DEFINITIONS AND THE MAIN RESULT

In the following text, we fix a positive integer m ; this integer will be called a *number of binary relations*. Our main case is $m = 1$, when we consider a single binary relation, and this binary relation is an order. However, our result is applicable to an arbitrary finite set of binary relations.

Definition 1. *By a space, we mean a set A with m binary relations $P_1(a, a'), \dots, P_m(a, a')$.*

Clarification. In this definition and in the following definitions, we only consider *crisp* relations – such as an order between the traditional fuzzy degrees of belief, i.e., between the numbers from the interval $[0, 1]$.

Terminological comment. Strictly speaking, a space is thus defined as a tuple (A, P_1, \dots, P_m) . Following the usual mathematical practice, we will, however, usually simplify our notations and simply talk about a space A – implicitly meaning the relations as well.

Definition 2. *By a first order property (or simply property, for short), we mean a (closed) formula F which is obtained from formulas $P_i(x, x')$ by using logical connectives $\vee, \&, \neg,$ and \rightarrow , and quantifiers $\exists x$ and $\forall x$.*

Comment. Most properties in which we may be interested are first order properties. For example, the property to be a total order has the form

$$\forall a \forall a' ((a \leq a') \vee (a' \leq a)).$$

The property to be a lattice L means that for every two elements a and a' there is a least upper bound and a greatest lower bound: $L \Leftrightarrow \bar{L} \& \underline{L}$, where

$$\begin{aligned} \bar{L} &\Leftrightarrow \forall a \forall a' \exists a^+ ((a \leq a^+) \& (a' \leq a^+) \& \\ &\forall a'' (((a \leq a'') \& (a' \leq a'')) \rightarrow a^+ \leq a''), \end{aligned}$$

and

$$\begin{aligned} \underline{L} &\Leftrightarrow \forall a \forall a' \exists a^- ((a^- \leq a) \& (a^- \leq a') \& \\ &\forall a'' (((a'' \leq a) \& (a'' \leq a')) \rightarrow a'' \leq a^-). \end{aligned}$$

Notations. When a property F is true for a space X , we will denote it by $F(X)$.

Definition 3. *By a product operation, we mean a collection of m propositional formulas that describe the relation $P_i((a_1, a_2), (a'_1, a'_2))$ between the elements $(a_1, a_2), (a'_1, a'_2) \in A_1 \times A_2$ in terms of the relations between the components $a_1, a'_1 \in A_1$ and $a_2, a'_2 \in A_2$ of these elements, i.e., in terms of the relations $P_1(a_1, a'_1), \dots, P_m(a_1, a'_1), P_1(a'_1, a_1), \dots, P_m(a'_1, a_1), P_1(a_2, a'_2), \dots, P_m(a_2, a'_2), P_1(a'_2, a_2), \dots, P_m(a'_2, a_2)$.*

Comment. The above formulas that define Cartesian and lexicographic products of partially ordered sets show that these

two product operations are examples of product operations in the sense of Definition 3.

Notational comment. For each operation, the space of all the elements is the set of all pairs $A_1 \times A_2$; so, in line with the above terminological comment, we will simply talk about the space $A_1 \times A_2$.

Main result. *There exists an algorithm that, given a product operation and a property F , generates a finite list of properties $F_{11}, F_{12}, F_{21}, F_{22}, \dots, F_{p1}, F_{p2}$, such that*

$$F(A_1 \times A_2) \Leftrightarrow ((F_{11}(A_1) \& F_{12}(A_2)) \vee \dots \vee (F_{p1}(A_1) \& F_{p2}(A_2))).$$

Comment. The above examples of checking when a Cartesian or a lexicographic products are total orders are examples of such equivalences. For example, for the Cartesian product, we have $p = 2$,

- $F_{11}(A_1)$ meaning that A_1 is a total order,
- $F_{12}(A_2)$ meaning that A_2 is a one-element set,
- $F_{21}(A_1)$ meaning that A_1 is a one-element set, and
- $F_{22}(A_2)$ meaning that A_2 is a total order.

Generalizations. As we will see from the proof, a similar algorithm can be formulated for a product of three or more spaces, and for the case when we allow ternary and higher order operations in the definition of a space.

III. PROOF

1°. Let us start with the desired property F . This property uses basic relations $P_i(a, a')$ between elements $a, a' \in A_1 \times A_2$ and quantifiers $\forall a$ and $\exists a$ over elements $a \in A_1 \times A_2$.

2°. Every element $a \in A_1 \times A_2$ is, by definition, a pair (a_1, a_2) in which a_1 is an element of the set A_1 and a_2 is an element of the set A_2 .

Let us explicitly replace each variable with such a pair.

3°. By definition of a product operation, each relation $P_i(a, a')$ – i.e., each relation $P_i((a_1, a_2), (a'_1, a'_2))$ – can be replaced by a propositional combination of relations between elements $a_1, a'_1 \in A_1$ and between elements $a_2, a'_2 \in A_2$.

Let us perform this replacement.

4°. Each quantifier can also be replaced by two quantifiers corresponding to components:

- $\forall(a_1, a_2)$ is equivalent to $\forall a_1 \forall a_2$, and
- $\exists(a_1, a_2)$ is equivalent to $\exists a_1 \exists a_2$.

Let us perform this replacement as well.

5°. As a result, we get an equivalent reformulation of the original formula F in which elementary formulas are relations between elements of A_1 or between A_2 and quantifiers are over A_1 or over A_2 .

We want to reduce this formula to the desired form

$$((F_{11}(A_1) \& F_{12}(A_2)) \vee \dots \vee (F_{p1}(A_1) \& F_{p2}(A_2))). \quad (1)$$

We will reduce this by induction. Elementary formulas are already of the desired form – provided, of course, that we allow free variables.

We will show that if we apply a propositional connective or a quantifier to a formula of this type, then we can reduce the result again to the formula of this type.

6°. When we apply propositional connectives to formulas of type (1), we thus get a propositional combination of the formulas of the type $F_{ij}(A_j)$. It is known that an arbitrary propositional combination can be described in a Disjunctive Normal Form (DNF), i.e., as a disjunction of conjunctions. Each conjunction combines properties related to A_1 and properties related to A_2 , i.e., has the form

$$G_1(A_1) \& \dots \& G_p(A_1) \& G_{p+1}(A_2) \& \dots \& G_q(A_2).$$

Thus, each conjunction has the form $G(A_1) \& G'(A_2)$, where

$$G(A_1) \Leftrightarrow (G_1(A_1) \& \dots \& G_p(A_1))$$

and

$$G'(A_2) \Leftrightarrow (G_{p+1}(A_2) \& \dots \& G_q(A_2)).$$

Thus, the disjunction of such properties has the desired form (1).

7°. When we apply an existential quantifier, e.g., $\exists a_1$, then we get a formula

$$\exists a_1 ((F_{11}(A_1) \& F_{12}(A_2)) \vee \dots \vee (F_{p1}(A_1) \& F_{p2}(A_2))).$$

It is known that $\exists a (A \vee B)$ is equivalent to $\exists a A \vee \exists a B$. Thus, the above formula is equivalent to a disjunction

$$\exists a_1 (F_{11}(A_1) \& F_{12}(A_2)) \vee \dots \vee \exists a_1 (F_{p1}(A_1) \& F_{p2}(A_2)).$$

If we prove that each term in this disjunction can be transformed into the desired form (1), then, by using the Part 6 of this proof, we will be able to conclude that the entire disjunction has the desired form. Thus, it is sufficient to prove that each formula

$$\exists a_1 (F_{i1}(A_1) \& F_{i2}(A_2)) \quad (2)$$

has the desired form. The term $F_{i2}(A_2)$ does not depend on a_1 at all, it is all about elements of A_2 . Thus, the formula (2) is equivalent to

$$(\exists a_1 F_{i1}(A_1)) \& F_{i2}(A_2),$$

i.e., to the formula

$$F'_{i1}(A_1) \& F_{i2}(A_2),$$

where

$$F'_{i1} \Leftrightarrow \exists a_1 F_{i1}(A_1)$$

is a formula depending only on the space A_1 .

The reduction is proven.

8°. When we apply a universal quantifier, e.g., $\forall a_1$, then we can use the fact that $\forall a_1 F$ is equivalent to $\neg \exists a_1 \neg F$. We have assumed that the formula F is of the desired type (1). Thus,

- by using Part 6 of this proof, we can conclude that the formula $\neg F$ can be reduced to the desired type;
- now, by applying Part 7 of this proof, we can conclude that the formula $\exists a_1 (\neg F)$ can also be reduced to the desired type;
- finally, by using Part 6 again, we conclude that the formula $\neg(\exists a_1 \neg F)$ can be reduced to the desired type.

9°. By induction, we can now conclude that the original formula can be reduced to the desired type. The main result is proven.

IV. EXAMPLE

To clarify our algorithm, let us apply it to the above simple case of checking whether a Cartesian product is totally ordered. In this case, the formula F that we want to check has the form

$$\forall a \forall a' ((a \leq a') \vee (a' \leq a)).$$

According to our algorithm, we first explicitly replace each variable $a, a' \in A_1 \times A_2$ with the corresponding pair. As a result, we get the following formula:

$$\forall (a_1, a_2) \forall (a'_1, a'_2)$$

$$(((a_1, a_2) \leq (a'_1, a'_2)) \vee ((a'_1, a'_2) \leq (a_1, a_2))).$$

Replacing the ordering relation on the Cartesian product with its definition, we get

$$\forall (a_1, a_2) \forall (a'_1, a'_2)$$

$$((a_1 \leq a'_1 \& a_2 \leq a'_2) \vee ((a'_1 \leq a_1 \& a'_2 \leq a_2))).$$

Replacing quantifiers over pairs with individual quantifiers, we get

$$\forall a_1 \forall a_2 \forall a'_1 \forall a'_2$$

$$((a_1 \leq a'_1 \& a_2 \leq a'_2) \vee ((a'_1 \leq a_1 \& a'_2 \leq a_2))).$$

By using the relation $\forall \Leftrightarrow \neg \exists \neg$, we get an equivalent form

$$\neg \exists a_1 \exists a_2 \exists a'_1 \exists a'_2$$

$$\neg((a_1 \leq a'_1 \& a_2 \leq a'_2) \vee (a'_1 \leq a_1 \& a'_2 \leq a_2)).$$

Moving negation inside the propositional formula, we get

$$\neg \exists a_1 \exists a_2 \exists a'_1 \exists a'_2$$

$$((a_1 \not\leq a'_1 \vee a_2 \not\leq a'_2) \& (a'_1 \not\leq a_1 \vee a'_2 \not\leq a_2)).$$

The propositional formula

$$(a_1 \not\leq a'_1 \vee a_2 \not\leq a'_2) \& (a'_1 \not\leq a_1 \vee a'_2 \not\leq a_2)$$

must now be transformed into a DNF form. The result is

$$(a_1 \not\leq a'_1 \& a'_1 \not\leq a_1) \vee$$

$$(a_1 \not\leq a'_1 \& a'_2 \not\leq a_2) \vee$$

$$(a_2 \not\leq a'_2 \& a'_1 \not\leq a_1) \vee$$

$$(a_2 \not\leq a'_2 \& a'_2 \not\leq a_2).$$

Thus, the formula

$$\exists a_1 \exists a_2 \exists a'_1 \exists a'_2 \\ \neg((a_1 \leq a'_1 \ \& \ a_2 \leq a'_2) \vee (a'_1 \leq a_1 \ \& \ a'_2 \leq a_2))$$

is equivalent to

$$F_1 \vee F_2 \vee F_3 \vee F_4,$$

where

$$F_1 \Leftrightarrow \exists a_1 \exists a_2 \exists a'_1 \exists a'_2 (a_1 \not\leq a'_1 \ \& \ a'_1 \not\leq a_1),$$

$$F_2 \Leftrightarrow \exists a_1 \exists a_2 \exists a'_1 \exists a'_2 (a_1 \not\leq a'_1 \ \& \ a'_2 \not\leq a_2),$$

$$F_3 \Leftrightarrow \exists a_1 \exists a_2 \exists a'_1 \exists a'_2 (a_2 \not\leq a'_2 \ \& \ a'_1 \not\leq a_1),$$

$$F_4 \Leftrightarrow \exists a_1 \exists a_2 \exists a'_1 \exists a'_2 (a_2 \not\leq a'_2 \ \& \ a'_2 \not\leq a_2).$$

By applying the quantifiers to the corresponding parts of the formulas, we get

$$F_1 \Leftrightarrow \exists a_1 \exists a'_1 (a_1 \not\leq a'_1 \ \& \ a'_1 \not\leq a_1),$$

$$F_2 \Leftrightarrow (\exists a_1 \exists a'_1 a_1 \not\leq a'_1) \ \& \ (\exists a_2 \exists a'_2 a'_2 \not\leq a_2),$$

$$F_3 \Leftrightarrow (\exists a_1 \exists a'_1 a'_1 \not\leq a_1) \ \& \ (\exists a_2 \exists a'_2 a_2 \not\leq a'_2),$$

$$F_4 \Leftrightarrow \exists a_2 \exists a'_1 \exists a'_2 (a_2 \not\leq a'_2 \ \& \ a'_2 \not\leq a_2).$$

Then, we again reduce

$$\neg(F_1 \vee F_2 \vee F_3 \vee F_4)$$

to DNF.

The result is more complex than the above criterion – because our algorithm does not use the fact that \leq is an order relation.

ACKNOWLEDGMENT

The authors are thankful to all the participants of the 14th GAMM-IMACS International Symposium on Scientific Computing, Computer Arithmetic and Validated Numerics SCAN'2010 (Lyon, France, September 27–30, 2010), especially to Vladik Kreinovich and Jürgen Wolff von Gudenberg, for valuable discussions.

APPENDIX: AUXILIARY RESULT

Formulation of the auxiliary result. Let us prove that for partial orders, the only product operations that always leads to a partial order on $A_1 \times A_2$ for which

$$(a_1 \leq_1 a'_1 \ \& \ a_2 \leq_2 a'_2) \rightarrow (a_1, a_2) \leq (a'_1, a'_2)$$

are Cartesian and lexicographic products.

Proof.

1°. According to the definition, whether $(a_1, a_2) \leq (a'_1, a'_2)$ depends on the two relation: the relation between a_1 and a'_1 and on the relation between a_2 and a'_2 . For each pair a_i and a'_i , we have four possible relations:

- the relation $a_i <_i a'_i$; we will denote this case by +;
- the relation $a'_i <_i a_i$; we will denote this case by –;
- the relation $a_i = a'_i$; we will denote this relation by =;
- and
- the relation $a_i \not\leq_i a'_i$ and $a'_i \not\leq_i a_i$; we will denote this relation by ||.

The case when we have relation R_1 for a_1 and a'_1 and relation R_2 for a_2 and a'_2 will be denoted by $R_1 R_2$. So, we have 16 possible pairs of relations: ++, +–, +=, +||, –+, ––, etc. To describe the product, it is sufficient to describe which of these 16 pairs correspond to $(a_1, a_2) \leq (a'_1, a'_2)$.

Due to the consistency requirement, pairs ++, +=, =+, and == always result in \leq , so it is sufficient to classify the remaining 12 pairs. If only these four pairs result in \leq , then we have the Cartesian product. So, to prove our theorem, it is sufficient to prove that if at least one other pair leads to \leq , then we get a lexicographic product. To prove this, let us consider the remaining 12 pairs one by one.

2°. Let us first consider pairs that contain –.

2.1°. Let us prove that the pair –– cannot lead to \leq . Indeed, when both A_1 and A_2 are real lines \mathbb{R} with the usual order, due to the fact that ++ leads to \leq , we get $(0, 0) \leq (1, 1)$, while due to the fact that –– leads to \leq , we get $(1, 1) \leq (0, 0)$. Hence, we have $(0, 0) \leq (1, 1)$ and $(1, 1) \leq (0, 0)$ but $(0, 0) \neq (1, 1)$ – a contradiction to antisymmetry.

2.2°. Similarly, the pair – = cannot lead to \leq because otherwise, for the same example $A_1 = A_2 = \mathbb{R}$, we would get $(0, 0) \leq (1, 0)$ and $(1, 0) \leq (0, 0)$ but $(0, 0) \neq (1, 0)$ – also a contradiction to antisymmetry.

2.3°. Let us now consider the pair – ||.

To prove that it cannot lead to \leq , we consider $A_1 = \mathbb{R}$ and $A_2 = \mathbb{R} \times \mathbb{R}$ with Cartesian order. In this case,

$$(0, 0) \parallel_2 (1, -2)$$

and $(1, -2) \parallel_2 (-1, -1)$. Thus, if $- \parallel$ leads to \leq , we have $(0, (0, 0)) \leq (-1, (1, -2))$ and $(-1, (1, -2)) \leq (-2, (-1, -1))$. Thus, due to transitivity of \leq , we get $(0, (0, 0)) \leq (-2, (-1, -1))$. On the other hand, due to consistency, from $-2 \leq_1 0$ and $(-1, -1) \leq_2 (0, 0)$, we conclude that $(-2, (-1, -1)) \leq (0, (0, 0))$ – a contradiction with antisymmetry.

2.4°. Similarly, pairs $= -$ and $\parallel -$ cannot lead to \leq . Thus, the only pairs containing $-$ that can potentially lead to \leq are pairs containing a $+$.

3°. Let us prove a similar property for pairs containing \parallel . We already know that pairs $\parallel -$ and $- \parallel$ cannot lead to \leq , so it is sufficient to consider pairs $\parallel =$, $= \parallel$, and $\parallel \parallel$.

3.1°. To prove that the pair $= \parallel$ cannot lead to \leq , let us consider the same case $A_1 = \mathbb{R}$ and $A_2 = \mathbb{R} \times \mathbb{R}$. In this case, due to

$$(0, 0) \parallel_2 (1, -2)$$

and $(1, -2) \parallel_2 (-1, -1)$, if $= \parallel$ leads to \leq , we have $(0, (0, 0)) \leq (0, (1, -2))$ and $(0, (1, -2)) \leq (0, (-1, -1))$. Thus, due to transitivity of \leq , we get

$$(0, (0, 0)) \leq (0, (-1, -1)).$$

On the other hand, due to consistency, from $0 \leq_1 0$ and $(-1, -1) \leq_2 (0, 0)$, we conclude that $(0, (-1, -1)) \leq (0, (0, 0))$ – a contradiction with antisymmetry.

3.2°. Similarly, it is possible to prove that the pair $\parallel =$ cannot lead to \leq .

3.3°. To prove that the pair $\parallel \parallel$ cannot lead to \leq , let us consider the case when $A_1 = A_2 = \mathbb{R} \times \mathbb{R}$. In this case, due to

$$(0, 0) \parallel_i (1, -2)$$

and $(1, -2) \parallel_i (-1, -1)$, if $\parallel \parallel$ leads to \leq , we have $((0, 0), (0, 0)) \leq ((1, -2), (1, -2))$ and $((1, -2), (1, -2)) \leq ((-1, -1), (-1, -1))$. Thus, due to transitivity of \leq , we get $((0, 0), (0, 0)) \leq ((-1, -1), (-1, -1))$. On the other hand, due to consistency, from $(-1, -1) \leq_i (0, 0)$, we conclude that $((-1, -1), (-1, -1)) \leq ((0, 0), (0, 0))$ – a contradiction with antisymmetry.

4°. Thus, due to Part 2 and 3 of this proof, the only additional pairs that can, in principle, lead to \leq are pairs containing $+$, i.e., pairs $+ -$, $+ \parallel$, $- +$, and $- \parallel$.

5°. Let us prove that the pair $+ -$ leads to \leq if and only if the pair $+ \parallel$ leads to \leq .

5.1°. Let us first prove that if the pair $+ -$ leads to \leq , then the pair $+ \parallel$ also leads to \leq .

Indeed, let us consider the case when $A_1 = \mathbb{R}$ and $A_2 = \mathbb{R} \times \mathbb{R}$. If $+ -$ leads to \leq , then $0 <_1 1$ and $(-1, -1) <_2 (0, 0)$

imply $(0, (0, 0)) \leq (1, (-1, -1))$. Due to consistency, $1 \leq_1 1$ and $(-1, -1) \leq_2 (-1, 1)$ lead to $(1, (-1, -1)) \leq (1, (-1, 1))$. Due to transitivity of \leq , we get $(0, (0, 0)) \leq (1, (-1, 1))$. In this case, \leq holds for a pair for which $0 <_1 1$ and $(0, 0) \parallel_2 (-1, 1)$, i.e., for a pair of type $+ \parallel$. By our definition of an order on the product, this means that \leq must hold for all pairs of this type, i.e., that the pair $+ \parallel$ indeed leads to \leq .

5.2°. Let us now prove that if the pair $+ \parallel$ leads to \leq , then the pair $+ -$ also leads to \leq .

Let us consider the same case $A_1 = \mathbb{R}$ and $A_2 = \mathbb{R} \times \mathbb{R}$. If $+ \parallel$ leads to \leq , then $0 <_1 1$ and $(1, -2) \parallel_2 (-1, -1)$ imply $(0, (0, 0)) \leq (1, (1, -2))$, and $1 <_1 2$ and $(0, 0) \parallel_2 (1, -2)$ imply $(1, (1, -2)) \leq (2, (-1, -1))$. Due to transitivity of \leq , we get $(0, (0, 0)) \leq (2, (-1, -1))$. In this case, \leq holds for a pair for which $0 <_1 2$ and $(-1, -1) <_2 (0, 0)$, i.e., for a pair of type $+ -$. By our definition of an order on the product, this means that \leq must hold for all pairs of this type, i.e., that the pair $+ -$ indeed leads to \leq .

6°. Similarly, we can prove that the pair $- +$ leads to \leq if and only if the pair $\parallel +$ leads to \leq . Thus, adding $+ -$ is equivalent to adding $+ \parallel$, and adding $- +$ is equivalent to adding $\parallel +$.

If we add $+ -$ (and hence $+ \parallel$), we get the lexicographic product $A_1 \times A_2$. If we add $- +$ (and hence $\parallel +$), we get the lexicographic product $A_2 \times A_1$. Thus, to complete the proof, it is sufficient to show that we cannot simultaneously add $+ -$ and $- +$.

7°. Let us prove that $+ -$ and $- +$ cannot simultaneously lead to \leq .

We will prove this by contradiction. Let us assume that adding both $+ -$ and $- +$ always leads to a consistent partial order. In this case, let us take $A_1 = A_2 = \mathbb{R}$. Since $+ -$ leads to \leq , the conditions $0 <_1 1$ and $-2 <_2 0$ lead to $(0, 0) \leq (1, -2)$. Similarly, since $- +$ leads to \leq , from $-1 <_1 1$ and $-2 <_2 -1$, we conclude that $(1, -2) \leq (-1, -1)$. By transitivity of \leq , we can now conclude that $(0, 0) \leq (-1, -1)$. However, due to consistency, $(-1, -1) \leq (0, 0)$ – a contradiction to antisymmetry.

The statement is proven, and so is the main result of this Appendix.
